This scanner technology produces high-quality images with rapid scan times, but at a relatively high dose of X-rays. In order to reduce the radiation dose during a scan, a dual-energy CT system has been developed that allows the scanner to switch between a lower energy beam (which can be used to quickly obtain a pre-contrast image) and a higher energy beam (which can be used to obtain a post-contrast image after administering contrast media) so that the high and low energy images can be combined to produce a single, high quality, contrast-enhanced image. In this case, the image is still reconstructed from a single projection set. Formation and functional properties of the histone-DNA interphase complex in chromatin of rat liver cells in vivo and in vitro. Using a cell-free system it was established that a major fraction of histone H1 is complexed with DNA in rat liver chromatin. To determine if this interaction is important in transcription in vivo, we have used the cytoplasmic inactivation of nuclei of hepatocytes by a non-ionic detergent. The inactivation of nuclei in vivo induced formation of histone-DNA complexes. The kinetics of inactivation, the yield of the bound histone and the apparent K_m were similar in in vivo and in vitro nuclei. Sodium dodecyl sulfate-gel electrophoresis of in vitro and in vivo chromatin showed that under the experimental conditions used there was no qualitative difference between the protease-sensitive complex of chromatin and an aggregate of nucleosomes in vivo. However, in vitro chromatin was more sensitive to deoxyribonuclease I than in vivo chromatin, suggesting a higher accessibility of chromatin to nuclease in vivo. The chromatin of inactivated hepatocytes was able to support transcription of globin genes, as determined by hybridisation of in vitro transcribed RNA to globin DNA sequences in cell-free systems. The transcriptional activity of chromatin of inactivated hepatocytes was greater than that of native chromatin, and the f678ea9f9e
